f_{cpe} = compressive stress in concrete due to effective prestress force only (after allowance for all prestress losses) at extreme fiber of section where tensile stress is caused by externally applied loads.

S_{nc} = section modulus for the extreme fiber of the monolithic or noncomposite section where tensile stress is caused by externally applied loads

S_c = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads

[LRFD 5.8.3.2] The reaction introduces compression into the end of the girder. Load between the CSS and the support is transferred directly to the support by compressive arching action without causing additional stresses in the stirrups. Hence, A_V/S in this region must be equal or greater than A_V/S at the critical section.

[LRFD 5.8.3.2] The reaction introduces compression into the end of the girder. Load between the CSS and the support is transferred directly to the support by compressive arching action without causing additional stresses in the stirrups. Hence, A_V/S in this region must be equal or greater than A_V/S at the critical section.

Slab Offset ("A" Dimension)

This table compares the input slab offset to the rounded computed slab offset required to have the least haunch depth be equal to the Fillet dimension. A failed status indicates that the top of the girder will encroach into the deck slab and the Slab Offset dimension should be refined.

Minimum Fillet Depth

This table compares the provided Fillet dimension to the minimum Fillet dimension specified in the girder library. A failed status indicates that the Fillet dimension is too small.

Sidewalk	0.279
Traffic Barrier	0.117
Pedestrian Live Load	0.106

Slab Load Applied Along Girder
Tributary width used to compute slab load is measured from top CL girder
Slab load is approximated with linear load segments applied along the length of the girder. Segments located outside of bearings are applied as point loads/moments at bearings.
Unit weight of Slab material is 0.150 kip/ft^3
Haunch weight includes effects of roadway geometry, and is measured along the centerline of the girder, but does not include a reduction for camber.

Prestress variability factor, γ_2 = 1.1
Ratio of specified minimum yield strength to ultimate tensile strength of the reinforcement,γ_3 = 1

$$M_{cr} = \gamma_3\left[\left(\gamma_1 f_r + \gamma_2 f_{cpe}\right)S_c - M_{dnc}\left(\frac{S_c}{S_{nc}} - 1\right)\right]$$

Segment 1 $f_r = 0.2400\lambda\sqrt{f'_c}$
f_{cpe} = compressive stress in concrete due to effective prestress force only (after allowance for all prestress losses) at extreme fiber of section where tensile stress is caused by externally applied loads.
S_{nc} = section modulus for the extreme fiber of the monolithic or noncomposite section where tensile stress is caused by externally applied loads
S_c = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads
M_{dnc} = total unfactored dead load moment acting on the monolithic or noncomposite section

Flexural cracking variability factor, γ_1 = 1.6

Prestress variability factor, γ_2 = 1.1

Ratio of specified minimum yield strength to ultimate tensile strength of the reinforcement, γ_3 = 0.67

$$M_{cr} = \gamma_3 \left[(\gamma_1 f_r + \gamma_2 f_{cpe}) S_c - M_{dnc} \left(\frac{S_c}{S_{nc}} - 1 \right) \right]$$

Segment 1 $f_r = 0.2400\lambda\sqrt{f'_c}$

f_{cpe} = compressive stress in concrete due to effective prestress force only (after allowance for all prestress losses) at extreme fiber of section where tensile stress is caused by externally applied loads.

S_{nc} = section modulus for the extreme fiber of the monolithic or noncomposite section where tensile stress is caused by externally applied loads

S_c = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads

M_{dnc} = total unfactored dead load moment acting on the monolithic or noncomposite section

Minimum Reinforcement [5.6.3.3] - Interval 17 - Open to Traffic

4.0 ABUTMENT DESIGN

ASSUMPTIONS

Overturning due to uneven girder placement for DC1 is not considered
DC2 and DW are assumed to apply evenly to bearing seat through integral abutment diaphragm
Bridge shall be evaluated for 100yr scour at Strength 1 & 500yr for Extreme Event 2 (EE 2)

Lateral Loads are converted into moments & vertical pile reactions

ASSUMPTIONS

Abutment Cap uses two span beam formulas for calculating moment and shear
Girder Reactions are evaluated midspan between piles.
Positive Moment uses single point load. Negative accounts for two in adjacent spans
Girder Reactions are located within most exterior piles
Weight of wingwalls on abutment cantilever produces smaller moments than interior

ASSUMPTIONS

Abutment Cap uses two span beam formulas for calculating moment and shear
Girder Reactions are evaluated midspan between piles.
Positive Moment uses single point load. Negative accounts for two in adjacent spans
Girder Reactions are located within most exterior piles
Weight of wingwalls on abutment cantilever produces smaller moments than interior
