RESULTS

Results for Superstructure Wind Pressures

Since individual span length is under 150ft and maximum height is below 33ft, design pressures use 100% of transverse (0deg) pressure + Longitudinal pressure as 25% of transverse. Both loads applied simultaneously. [3.8.1.2.3a]

Continuity [5.12.3.3.5]

	f_b (KSI)	Boundary Condition	Is Compressive?
Abut 1	0.000	Hinged	No
Pier 2	-1.224	Continuous	Yes
Abut 3	0.000	Hinged	No

f_b is the calcuated stress at the bottom of the continuity diaphragm for the combination of superimposed permanent loads and 50% live load
Continuous connections are fully effective.
Continuity is accounted for in Service and Strength Limit States.

[LRFD 5.8.3.2] The reaction introduces compression into the end of the girder. Load between the CSS and the support is transferred directly to the support by compressive arching action without causing additional stresses in the stirrups. Hence, A_V/S in this region must be equal or greater than A_V/S at the critical section.

Haunch Geometry Checks

Note: Specification Checks for Haunch Geometry are Disabled in the Project Criteria. All Status values will be reported as N/A.

Slab Offset ("A" Dimension)

This table compares the input slab offset to the rounded computed slab offset required to have the least haunch depth be equal to the Fillet dimension. A failed status indicates that the top of the girder will encroach into the deck slab and the Slab Offset dimension should be refined.

Minimum Fillet Depth

This table compares the provided Fillet dimension to the minimum Fillet dimension specified in the girder library. A failed status indicates that the Fillet dimension is too small.

Loading Details

Uniform Loads Applied Along the Entire Girder

Load Type	w (kip/ft)
Girder	0.740
Sidewalk	0.279
Traffic Barrier	0.117
Pedestrian Live Load	0.106

Slab Load Applied Along Girder
Tributary width used to compute slab load is measured from top CL girder
Slab load is approximated with linear load segments applied along the length of the girder. Segments located outside of bearings are applied as point loads/moments at bearings.
Unit weight of Slab material is 0.150 kip/ft^3
Haunch weight includes effects of roadway geometry, and is measured along the centerline of the girder, but does not include a reduction for camber.

Prestress variability factor, γ_2 = 1.1

Ratio of specified minimum yield strength to ultimate tensile strength of the reinforcement, γ_3 = 0.67

$$M_{cr} = \gamma_3 \left[(\gamma_1 f_r + \gamma_2 f_{cpe}) S_c - M_{dnc} \left(\frac{S_c}{S_{nc}} - 1 \right) \right]$$

Segment 1 $f_r = 0.2400\lambda\sqrt{f'_c}$

f_{cpe} = compressive stress in concrete due to effective prestress force only (after allowance for all prestress losses) at extreme fiber of section where tensile stress is caused by externally applied loads.

S_{nc} = section modulus for the extreme fiber of the monolithic or noncomposite section where tensile stress is caused by externally applied loads

S_c = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads

M_{dnc} = total unfactored dead load moment acting on the monolithic or noncomposite section

Girder Spacing Datum:
(1) Measured normal to the alignment at the abutment/pier line
(2) Measured normal to the alignment at the centerline of bearing
(3) Measured at and along the abutment/pier line
(4) Measured at and along the centerline of bearing

Girder spacing is measured at the work point elevation, which is at top centerline of girder.
Girder orientation is set plumb

[LRFD 5.8.3.2] The reaction introduces compression into the end of the girder. Load between the CSS and the support is transferred directly to the support by compressive arching action without causing additional stresses in the stirrups. Hence, A_V/S in this region must be equal or greater than A_V/S at the critical section.

Slab Offset ("A" Dimension)

This table compares the input slab offset to the rounded computed slab offset required to have the least haunch depth be equal to the Fillet dimension. A failed status indicates that the top of the girder will encroach into the deck slab and the Slab Offset dimension should be refined.

Span	Girder	Provided (in)	Required (in)	Status	Notes

Minimum Fillet Depth

This table compares the provided Fillet dimension to the minimum Fillet dimension specified in the girder library. A failed status indicates that the Fillet dimension is too small.

Prestress variability factor, γ_2 = 1.1

Ratio of specified minimum yield strength to ultimate tensile strength of the reinforcement,γ_3 = 1

$$M_{cr} = \gamma_3\left[\left(\gamma_1 f_r + \gamma_2 f_{cpe}\right)S_c - M_{dnc}\left(\frac{S_c}{S_{nc}} - 1\right)\right]$$

Segment 1 $f_r = 0.2400\lambda\sqrt{f'_c}$

f_{cpe} = compressive stress in concrete due to effective prestress force only (after allowance for all prestress losses) at extreme fiber of section where tensile stress is caused by externally applied loads.

S_{nc} = section modulus for the extreme fiber of the monolithic or noncomposite section where tensile stress is caused by externally applied loads

S_c = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads

M_{dnc} = total unfactored dead load moment acting on the monolithic or noncomposite section

Flexural cracking variability factor, γ_1 = 1.6

Prestress variability factor, γ_2 = 1.1

Ratio of specified minimum yield strength to ultimate tensile strength of the reinforcement, γ_3 = 0.67

$$M_{cr} = \gamma_3 \left[(\gamma_1 f_r + \gamma_2 f_{cpe}) S_c - M_{dnc} \left(\frac{S_c}{S_{nc}} - 1 \right) \right]$$

Segment 1 $f_r = 0.2400\lambda\sqrt{f'_c}$

f_{cpe} = compressive stress in concrete due to effective prestress force only (after allowance for all prestress losses) at extreme fiber of section where tensile stress is caused by externally applied loads.

S_{nc} = section modulus for the extreme fiber of the monolithic or noncomposite section where tensile stress is caused by externally applied loads

S_c = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads

M_{dnc} = total unfactored dead load moment acting on the monolithic or noncomposite section

Continuity [5.12.3.3.5]

	f_b (KSI)	Boundary Condition	Is Compressive?
Abut 1	0.000	Hinged	No
Pier 2	-1.056	Continuous	Yes
Abut 3	0.000	Hinged	No

f_b is the calcuated stress at the bottom of the continuity diaphragm for the combination of superimposed permanent loads and 50% live load

Continuous connections are fully effective.

Continuity is accounted for in Service and Strength Limit States.

[LRFD 5.8.3.2] The reaction introduces compression into the end of the girder. Load between the CSS and the support is transferred directly to the support by compressive arching action without causing additional stresses in the stirrups. Hence, A_V/S in this region must be equal or greater than A_V/S at the critical section.

Slab Offset ("A" Dimension)

This table compares the input slab offset to the rounded computed slab offset required to have the least haunch depth be equal to the Fillet dimension. A failed status indicates that the top of the girder will encroach into the deck slab and the Slab Offset dimension should be refined.

Minimum Fillet Depth

This table compares the provided Fillet dimension to the minimum Fillet dimension specified in the girder library. A failed status indicates that the Fillet dimension is too small.

Slab Load Applied Along Girder
Tributary width used to compute slab load is measured from top CL girder
Slab load is approximated with linear load segments applied along the length of the girder. Segments located outside of bearings are applied as point loads/moments at bearings.

Flexural cracking variability factor, γ_1 = 1.6

Prestress variability factor, γ_2 = 1.1

Ratio of specified minimum yield strength to ultimate tensile strength of the reinforcement,γ_3 = 1

$$M_{cr} = \gamma_3\left[\left(\gamma_1 f_r + \gamma_2 f_{cpe}\right)S_c - M_{dnc}\left(\frac{S_c}{S_{nc}} - 1\right)\right]$$

Segment 1 $f_r = 0.2400\lambda\sqrt{f'_c}$

f_{cpe} = compressive stress in concrete due to effective prestress force only (after allowance for all prestress losses) at extreme fiber of section where tensile stress is caused by externally applied loads.

S_{nc} = section modulus for the extreme fiber of the monolithic or noncomposite section where tensile stress is caused by externally applied loads

S_c = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads

M_{dnc} = total unfactored dead load moment acting on the monolithic or noncomposite section

Flexural cracking variability factor, γ_1 = 1.6

Prestress variability factor, γ_2 = 1.1

Ratio of specified minimum yield strength to ultimate tensile strength of the reinforcement, γ_3 = 0.67

$$M_{cr} = \gamma_3 \left[(\gamma_1 f_r + \gamma_2 f_{cpe}) S_c - M_{dnc} \left(\frac{S_c}{S_{nc}} - 1 \right) \right]$$

Segment 1 $f_r = 0.2400\lambda\sqrt{f'_c}$

f_{cpe} = compressive stress in concrete due to effective prestress force only (after allowance for all prestress losses) at extreme fiber of section where tensile stress is caused by externally applied loads.

S_{nc} = section modulus for the extreme fiber of the monolithic or noncomposite section where tensile stress is caused by externally applied loads

S_c = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads

M_{dnc} = total unfactored dead load moment acting on the monolithic or noncomposite section

Continuity [5.12.3.3.5]

	f_b (KSI)	Boundary Condition	Is Compressive?
Abut 1	0.000	Hinged	No
Pier 2	-1.056	Continuous	Yes
Abut 3	0.000	Hinged	No

f_b is the calcuated stress at the bottom of the continuity diaphragm for the combination of superimposed permanent loads and 50% live load
Continuous connections are fully effective.
Continuity is accounted for in Service and Strength Limit States.

[LRFD 5.8.3.2] The reaction introduces compression into the end of the girder. Load between the CSS and the support is transferred directly to the support by compressive arching action without causing additional stresses in the stirrups. Hence, A_V/S in this region must be equal or greater than A_V/S at the critical section.

Slab Offset ("A" Dimension)

This table compares the input slab offset to the rounded computed slab offset required to have the least haunch depth be equal to the Fillet dimension. A failed status indicates that the top of the girder will encroach into the deck slab and the Slab Offset dimension should be refined.

Minimum Fillet Depth

This table compares the provided Fillet dimension to the minimum Fillet dimension specified in the girder library. A failed status indicates that the Fillet dimension is too small.

Flexural cracking variability factor, γ_1 = 1.6
Prestress variability factor, γ_2 = 1.1
Ratio of specified minimum yield strength to ultimate tensile strength of the reinforcement,γ_3 = 1

$$M_{cr} = \gamma_3\left[\left(\gamma_1 f_r + \gamma_2 f_{cpe}\right)S_c - M_{dnc}\left(\frac{S_c}{S_{nc}} - 1\right)\right]$$

Segment 1 $f_r = 0.2400\lambda\sqrt{f'_c}$
f_{cpe} = compressive stress in concrete due to effective prestress force only (after allowance for all prestress losses) at extreme fiber of section where tensile stress is caused by externally applied loads.
S_{nc} = section modulus for the extreme fiber of the monolithic or noncomposite section where tensile stress is caused by externally applied loads
S_c = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads
M_{dnc} = total unfactored dead load moment acting on the monolithic or noncomposite section

Flexural cracking variability factor, $\gamma_1 = 1.6$

Prestress variability factor, $\gamma_2 = 1.1$

Ratio of specified minimum yield strength to ultimate tensile strength of the reinforcement, $\gamma_3 = 0.67$

$$M_{cr} = \gamma_3 \left[(\gamma_1 f_r + \gamma_2 f_{cpe}) S_c - M_{dnc} \left(\frac{S_c}{S_{nc}} - 1 \right) \right]$$

Segment 1 $f_r = 0.2400\lambda\sqrt{f'_c}$

f_{cpe} = compressive stress in concrete due to effective prestress force only (after allowance for all prestress losses) at extreme fiber of section where tensile stress is caused by externally applied loads.

S_{nc} = section modulus for the extreme fiber of the monolithic or noncomposite section where tensile stress is caused by externally applied loads

S_c = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads

M_{dnc} = total unfactored dead load moment acting on the monolithic or noncomposite section

[LRFD 5.8.3.2] The reaction introduces compression into the end of the girder. Load between the CSS and the support is transferred directly to the support by compressive arching action without causing additional stresses in the stirrups. Hence, A_V/S in this region must be equal or greater than A_V/S at the critical section.

[LRFD 5.8.3.2] The reaction introduces compression into the end of the girder. Load between the CSS and the support is transferred directly to the support by compressive arching action without causing additional stresses in the stirrups. Hence, A_V/S in this region must be equal or greater than A_V/S at the critical section.

Slab Offset ("A" Dimension)

This table compares the input slab offset to the rounded computed slab offset required to have the least haunch depth be equal to the Fillet dimension. A failed status indicates that the top of the girder will encroach into the deck slab and the Slab Offset dimension should be refined.

Minimum Fillet Depth

This table compares the provided Fillet dimension to the minimum Fillet dimension specified in the girder library. A failed status indicates that the Fillet dimension is too small.

Traffic Barrier	0.117
Pedestrian Live Load	0.106

Slab Load Applied Along Girder
Tributary width used to compute slab load is measured from top CL girder
Slab load is approximated with linear load segments applied along the length of the girder. Segments located outside of bearings are applied as point loads/moments at bearings.
Unit weight of Slab material is 0.150 kip/ft^3
Haunch weight includes effects of roadway geometry, and is measured along the centerline of the girder, but does not include a reduction for camber.
